N35 - SOLUTIONS

K_{sp}

N35 - SOLUTIONS K_{sp}

Target: I can perform K_{sp} calculations to determine the solubility of different salts.

Just application of old info!

Just application of old info!

Equilibrium constants and ICE Tables.

Only real difference is that your reactant is always a solid so it doesn't show up in the Law of Mass Action.

But that isn't "new" – we've known that forever!

Solubility Chart

A solubility chart is a qualitative distinction!

When we say insoluble, we mean so little dissociates that it isn't practical. A few will still dissociate!

Can do math to see how much dissociates.

Strontium sulfate	SrSO ₄	3.4 x 10 ⁻⁷
Zinc sulfide	ZnS	2.0 x 10 ⁻²⁵

Ksp isn't always the most useful value

You can't always <u>directly</u> compare the solubility of substances based on their K_{sp} values because the stoichiometry comes into play also.

AgCl	VS	CaCl ₂
2 ions		3 ions

Instead we will use a value that we calculate that allows us to compare the solubility of two compounds more directly.

Expressing Solubility

We typically describe the solubility as how much solute can you dissolve in how much solvent.

Moles / Liter - 0.25 moles will dissociate in 1 L sol'n Grams / Liter Etc...

(Always check what units it wants answers in!)

This value is called the Molar Solubility Usually represented by "s"

Solving Solubility Problems

Calculate molar solubility for Agl at 25°C, $K_{sp} = 1.5 \times 10^{-16}$

<u></u>		j + i(aq)
I	0	0
С	+X	+X
E	×	×

$$Agl(s) \rightarrow Ag^{+}(aq) + I^{-}(aq)$$

$$K_{sp} = [Ag^+][I^-]$$

Nothing on the denominator because the reactant was a solid!

Meaning:

 1.2×10^{-8} moles of Ag⁺ and I⁻ can be present per 1 L of sol'n before the sol'n is saturated.

Or...you can get 1.2×10^{-8} moles of Agl to dissociate per L of sol'n

 $1.5 \times 10^{-16} = \times^2$

X = s = molar solubility of Agl in mol/L

 $= 1.2 \times 10^{-8} M$

Solving Solubility Problems

Calculate molar solubility for Agl at 25°C, $K_{sp} = 1.5 \times 10^{-16}$

	רא נמע	j + i(aq)
I	0	0
С	+S	+S
E	S	S

$$Agl(s) \rightarrow Ag^{+}(aq) + I^{-}(aq)$$

$$K_{sp} = [Ag^+][I^-]$$

Nothing on the denominator because the reactant was a solid!

Meaning:

 1.2×10^{-8} moles of Ag⁺ and I⁻ can be present per 1 L of sol'n before the sol'n is saturated.

Or...you can get 1.2×10^{-8} moles of Agl to dissociate per L of sol'n

 $1.5 \times 10^{-16} = s^2$

s = molar solubility of Agl in mol/L

 $= 1.2 \times 10^{-8} M$

Solving Solubility Problems When Not 1:1

Calculate molar solubility for PbCl₂ at 25°C, $K_{sp} = 1.6 \times 10^{-5}$

Meaning:

1.6 x 10^{-2} mol of Pb^{2+} and 3.2 x 10^{-2} mol of CF can be present per 1 L of sol'n before the sol'n is saturated.

Or...you can get 1.6×10^{-2} moles of $PbCl_2$ to dissociate per L of solution

$\begin{array}{c|c} \mathsf{PbCl}_2(s) \xrightarrow{} \mathsf{Pb}^{2+}(\mathsf{aq}) + 2\mathsf{Cl}^{-}(\mathsf{aq}) \\ \hline & \mathsf{I} & \mathsf{O} & \mathsf{O} \\ & \mathsf{C} & +\mathsf{s} & +2\mathsf{s} \\ \end{array} \begin{array}{c|c} \mathsf{Be} \\ \mathsf{s} \end{array}$

S

2s

Be careful with the stoichiometry!

$$1.6 \times 10^{-5} = (s)(2s)^2 = 4s^3$$

F

 $s = molar solubility of PbCl_2 in mol/L = 1.6 x 10^{-2} M$

The molar solubility of Pbl_2 is 1.50×10^{-3} M. Calculate the value of K_{sp} for Pbl_2 .

3.38E⁻⁹ **B** 4.50E⁻⁶ 1.35E⁻⁸ C **D** 1.50E⁻³ none of these E

The molar solubility of Pbl_2 is 1.50×10^{-3} M. Calculate the value of K_{sp} for Pbl_2 .

Will Something Precipitate?

Have to check Q versus K !

Q < K _{sp}	No precipitate yet! The solution is unsaturated. All ions are still dissociated.
Q = K _{sp}	No precipitate yet! The solution is saturated. The maximum amount of ions are dissociated.
Q > K _{sp}	A precipitate will form! The maximum amount of ions are already dissociated, so the extra will "crash out" as a solid precipitate.

Note Supersaturated solutions have $Q > K_{sp}$ but a ppt hasn't crashed out yet because it was made at a higher temperature and slowly cooled down. It is unstable and the ppt will crash out once the sol'n is disturbed.

https://youtu.be/uxCgxBr6mQY

Common Ion Effect

What happens to the solubility of a substance if one of its ions is already present in the solution?

Will the solubility increase or decrease????

It decreases!

Let's redo this problem but this time let's have some I⁻ already in the solution - x should For the salt AgI at 25°C, $K_{sp} = 1.5 \times 10^{-16}$ AgI(s) \rightarrow Ag⁺(aq) + I⁻(aq) s = solubility of AgI in mol/L = 1.2 x 10⁻⁸ M

in the solution. x should end up less than 1.2 x 10⁻⁸ mol/L

Solving Solubility with a Common Ion

For the salt AgI at 25°C, $K_{sp} = 1.5 \times 10^{-16}$ What is its solubility in 0.05 M Nal?

$Agl(s) \rightarrow Ag^{+}(aq) + I^{-}(aq)$

I	0	0.05
С	+ S	+ S
E	S	0.05+s

5% rule!

 $1.5 \ge 10^{-16} = (s)(0.05+s) \cong (s)(0.05)$

s = solubility of Agl in mol/L = $3.0 \times 10^{-15} M$

Qualitatively describing how adding something changes solubility

Another Salt: Look to see if the dissociated ions are in common

t:	BaCl ₂ + NaCl	BaCl ₂ + NaF
if Ited	Ba ²⁺ 2Cl ⁻ Na ⁺ Cl ⁻	Ba ²⁺ 2Cl ⁻ Na ⁺ F ⁻
	Cl ⁻ is in common with BaCl ₂ , so it will decrease the solubility.	F ⁻ is NOT in common with BaCl ₂ , so it will not change the solubility.

Qualitatively describing how adding something changes solubility

Adding an Acid: Look to see if the dissociated ions will react with one of the ions from the salt.

d:	$BaCl_2 + HNO_3$	$CaF_2 + HNO_3$
	Ba ²⁺ 2Cl ⁻ H ⁺ NO ₃ ⁻	Ca ²⁺ 2F ⁻ H ⁺ NO ₃ ⁻
d		
	H ⁺ and Cl ⁻ make a	H ⁺ and F ⁻ make a weak
Ż	strong acid	acid which doesn't
	which stays	dissociate fully!
	dissociated.	Removes F⁻ ions from
	Doesn't affect the	solution. Increases the
	solubility of	solubility of CaF ₂ ,
	BaCl ₂	trying to replace F ⁻ ions

In which solution is BaSO₄ most soluble?

A solution that is 0.10 M in $Ba(NO_3)_2$

A solution that is 0.10 M in Na₂SO₄

A solution that is 0.10 M in NaNO₃

	Y)
×	_

None of these, solubility never changes, it is a set value

In which solution is BaSO₄ most soluble?

A solution that is 0.10 M in $Ba(NO_3)_2$

A solution that is 0.10 M in Na₂SO₄

C A solution that is 0.10 M in NaNO₃

None of these, solubility never changes, it is a set value

The others have common ions that would drive equilibrium position to the left, resulting in less dissociation of the ions

Complex ion - a charged species composed of:

- 1. A metallic cation
- 2. Ligands

Ligand – Lewis bases that have a lone electron pair that can form a covalent bond with an empty orbital belonging to the metallic cation

NH₃, CN⁻, and H₂O are Common Ligands

<u>***NOTE*</u>** A lot of Lewis acids/bases act as ligands. They are often involved in solubility problems, which is why we tend to put K_{sp} in the Acid Base chapter and not always Equilibrium or Solutions chapters.</u>

Coordination Number

Coordination number

The number of ligands attached to the cation

• 2, 4, and 6 are the most common coordination numbers

Coordination #	Example(s)
2	$Ag(NH_3)_2^+$
4	$CoCl_{4}^{2-}$ $Cu(NH_{3})_{4}^{2+}$
6	$Co(H_2O)_6^{2+}$ Ni(NH ₃) ₆ ²⁺

Complex Ions and Solubility

$$AgCl(s) \leftrightarrows Ag^{+} + Cl^{-} \qquad K_{sp} = 1.6 \times 10^{-10}$$

$$Ag^{+} + NH_{3} \leftrightarrows Ag(NH_{3})^{+} \qquad K_{1} = 2.1 \times 10^{3}$$

$$Ag(NH_{3})^{+} NH_{3} \leftrightarrows Ag(NH_{3})_{2}^{+} \qquad K_{2} = 8.2 \times 10^{3}$$

$$AgCl + 2NH_{3} \leftrightarrows Ag(NH_{3})_{2}^{+} + Cl^{-} \qquad K = K_{sp} \cdot K_{1} \cdot K_{2}$$

$$K = 2.8 \times 10^{-3} = \frac{[Ag(NH_{3})_{2}^{+}][Cl^{-}]}{[NH_{3}]^{2}}$$

Some more pretty precipitation videos if you are interested

Precipitation

And in case of the local division of the loc
