

# **N19 - VSEPR and the 3D Geometry of Molecules**

## **Target:**

**I can identify the 3-dimensional  
shape of molecules.**

# VSEPR Model

(Valence Shell Electron Pair Repulsion)

- The structure around a given atom is determined (*mostly*) by **minimizing electron pair repulsions.**
- They try to maximize the distance between electrons

# The Effect of Lone Pairs

- Lone pair = “occupy more space”
- This affects the bond angles, making the bonding pair angles smaller than expected.
- Pushes the atoms out of the way
- Relative sizes of repulsive force interactions is as follows:

**Lowest:** Bonding Pair – Bonding Pair

**Medium:** Lone Pair – Bonding Pair

**Highest:** Lone Pair – Lone Pair

**Hybridization** is the combining of two or more orbitals of nearly equal energy within the same atom into orbitals of equal energy.

# sp Hybrid Orbitals

One s orbital combines with one p orbital  
Two p orbitals are left the same

# sp<sup>2</sup> Hybrid Orbitals

One s orbital combines with two p orbitals  
One p orbital remains unchanged.

# sp<sup>3</sup> Hybrid Orbitals

One s orbital combines with three p orbitals

## VSEPR – AXE Method

- The **A** represents the central atom.
- The **X** represents how many bonded atoms.
- The **E** represents the number of lone electron pairs present on the central atom.
- The sum of **X** and **E**, sometimes known as the steric number.
